

Question 1:

Employees

Column Name	Type
emp_id	int
emp_name	varchar
dept_id	int
salary	int

Departments

Column Name	Type
dept_id	int
dept_name	varchar
location	varchar

Write an SQL query to display the **department name, employee name, and salary** of all employees who work in the **"IT" department** and have a salary **greater than the average salary of employees in their department**.

Question 2

You are given a table **Products** with the following structure:

Column Name	Type
product_id	int
store1	int
store2	int
store3	int

- Product_id is the primary key (unique for each product).
- Each row indicates the price of a product in three different stores (Store1, store2 and store3).
- If a product is not available in a store, the price will be stored as `NULL` for that store's column.

Write a solution to rearrange the Products table so that each row has (product_id, store, price). If a product is not available in a store, do **not** include a row with that product_id and store combination in the result table.

Example

Input:

Products table:

+-----+-----+-----+				
product_id	store1	store2	store3	
+-----+-----+-----+				
0	95	100	105	
1	70	null	80	

Output:

+-----+-----+-----+				
product_id	store	price		
+-----+-----+-----+				
0	store1	95		
0	store2	100		
0	store3	105		
1	store1	70		
1	store3	80
